ABSTRACT

We propose that managers adept at thinking about their cultural assumptions (cultural metacognition) are more likely than others to develop affect-based trust in their relationships with people from different cultures, enabling creative collaboration. Study 1, a multi-rater assessment of managerial performance, found that managers higher in metacognitive cultural intelligence (CQ) were rated as more effective in intercultural creative collaboration by managers from other cultures. Study 2, a social network survey, found that managers lower in metacognitive CQ engaged in less sharing of new ideas in their intercultural ties but not intracultural ties. Study 3 required participants to work collaboratively with a non-acquaintance from another culture and found that higher metacognitive CQ engendered greater idea sharing and creative performance, so long as they were allowed a personal conversation prior to the task. The effects of metacognitive CQ in enhancing creative collaboration were mediated by affect-based trust in Studies 2 and 3.

Introduction

Research in management and organizational behavior has increasingly focused on individual differences that enable managers to succeed in intercultural interactions (e.g., Ang & Van Dyne, 2008; Earley & Ang, 2003; Imai & Gelfand, 2010; Johnson, Lenartowicz, & Apud, 2006; Shapiro, Ozanne, & Saatcioglu, 2008; Thomas, 2006). One long standing theme is that intercultural success accrues from being mindful of one’s own and others’ assumptions when interacting with individuals from different cultures (Johnson, Cullen, Sakano, & Takenouchi, 1996; LaBahn & Harich, 1997). This skill in reflecting on cultural assumptions in order to prepare for, adapt to, and learn from intercultural interactions is increasingly referred to as cultural metacognition (Earley & Ang, 2003; Earley, Ang, & Tan, 2006; Klafehn, Banerjee, & Chiu, 2008; Thomas, 2006; Van Dyne, Ang, Ng, & Koh, 2008). Under the rubric of cultural intelligence or CQ, instruments have been developed to measure individual variations in cultural metacognition, assessed in terms of self-reported awareness of one’s cultural assumptions, planning for upcoming intercultural activities, checking the applicability of and adjusting one’s assumptions during a given interaction, and updating assumptions after each experience (Ang, Van Dyne, & Tan, 2011; Earley & Ang, 2003).

In this research, we explore the role of cultural metacognition in intercultural creative collaboration. Although collaboration can occur in larger groups, we focus for the sake of clarity on dyadic collaboration. Just like scientists, businesspeople often share ideas and brainstorm solutions to a problem with others in their professional network. Innovative products and deals are developed when such conversations bring together disparate ideas that have never previously been connected, for example using alloys developed by bicycle racers to design lighter wheelchairs, or finding a market for South Pacific coconut juice among American urban professionals (Sutton & Hargadon, 1996). Accordingly, creative potential in a collaborative dyad comes from the differences between the two people—surface demographic differences such as nationality or ethnic background correspond to deeper differences in people’s knowledge of the world, their capabilities, and connections. Interactions with people from different cultures can expose one to ideas that are not redundant with one’s own; the exchange of ideas in the conversation could result in a novel combination of ideas.

The creative potential in cross-cultural relationships, however, often goes unrealized. Sharing one’s knowledge and insights with another person, an inherent aspect of creative collaboration, entails making oneself vulnerable to the other. Hence, sharing new ideas requires trust, which can be defined as confidence in relying on another person (Luhmann, 1979; McAllister, 1995). New ideas that one shares could be stolen if they are good or ridiculed if they are bad (Diehl & Stroebe, 1987; Diehl & Stroebe, 1991). Sharing new ideas depends a lot on feelings for the other and on the other’s concern for oneself. This set of sentiments is called affect-based...
trust (McAllister, 1995) and has been long been studied by researchers interested in trust as a feeling (Lewis & Weigert, 1985; Rempel, Holmes, & Zanna, 1985). While collaboration on a mundane task simply requires sharing the labor, creative collaboration involves the exchange of ideas to develop a novel solution that neither person in the dyad would have crafted on their own. Affect-based trust lubricates the exchange of new ideas that propels creative collaboration. In sum, the creative potential of cross-cultural interaction flows through affect-based trust.

We propose that individuals higher in cultural metacognition are more likely to develop affect-based trust in their intercultural interactions and relationships. When getting to know a person from a different culture, the other may misunderstand comments, misconstrue jokes, and decline invitations because of cultural differences. Reflective thinking about cultural differences enables one to interpret these awkward moments for what they are and not let them be impediments to closeness. The habit and skill of thinking about one's own and other's culturally based assumptions presumably enables individuals to communicate better, to put people at ease, and to avoid misunderstandings and tensions. Affect-based trust is distinguished from cognition-based trust, defined as the perception of the other's reliability and competence (Butler, 1991; Cook & Wall, 1980; Zucker, 1986). Cognition-based trust is founded on rational evidence-based assessments of the other's ability and track record. Both kinds of trust may be more difficult to develop in intercultural relationships (Branzei, Vertinsky, & Camp, 2007; Jiang, Chua, Kotabe, & Murray, 2011; Rockstuhl & Fang, 2008). Cognitive processes such as stereotyping can undermine positive judgments about competence, whereas affective processes such as anxiety can hinder emotional openness and sharing (Gelfand, Erez, & Aycan, 2007; Mackie & Hamilton, 1993). For reasons that we shall elaborate, we contend that affect-based trust, rather than cognition-based trust, is pivotal in the link between individual differences in cultural metacognition and creative collaboration.

We examined these hypotheses using multiple research methods. Study 1 used a multi-rater survey to assess managers' intercultural collaboration from the perspective of work colleagues from different cultures. We tested whether managers with high (vs. low) cultural metacognition achieve more creative collaboration in their intercultural relationships. In Study 2, we surveyed managers about their professional networks, assessing creative collaboration in terms of their creativity-related communication (sharing of new ideas) in all their key professional relationships. An important feature of Study 2 is that we explicitly compare the effects of cultural metacognition on trust and creative collaboration between intracultural relationships (with someone of the same cultural background) and intercultural relationships (with someone of different cultural background). This approach allows us to examine whether cultural metacognition taps mental habits specific to bridging cultural differences or perspective taking habits that help relationships in general. Study 3 used a laboratory experiment to manipulate the conditions that facilitate the development of the mediating mechanism—affect-based trust. Our objective is to show that the effects of cultural metacognition depend on conditions that enable affect-based trust; even if individuals have this important strength they will not develop creative collaboration if the conditions do not facilitate affect-based trust.

Taken together, these studies make several contributions. First, we present evidence that individuals' cultural metacognition is linked to success in intercultural creative collaborations. This basic finding contributes to the growing literature on cultural intelligence, showing how specific aspects of intercultural competence foster managerial performance needed in a global workplace. Second, we explicate a key psychological mechanism that underlies the relationship between cultural metacognition and creative collaboration—intercultural affect-based trust. This finding pushes theoretical boundaries in creativity research through focusing on intercultural creative collaboration at a dyadic level of analysis. Organizational behavior scholars have called for more in-depth theorizing on how individuals leverage interpersonal interactions for creativity (George, 2007). Yet little extant research has examined creativity at the dyadic level, especially across cultural lines. Our research fills this gap, introducing three complementary methods for studying creativity at the dyadic level. Third, the present research expands on emerging theory that connects cultural diversity with creativity (Leung, Maddux, Galinsky, & Chiu, 2008) by investigating the conditions that allow people from different cultures to collaborate creatively. We elaborate on these and other contributions in the discussion section.

**Cultural metacognition and intercultural collaboration**

Scholars have long studied factors that foster intercultural interactions and collaborations (Gertsen & Säderberg, 2011; Irani & Dourish, 2009; Johnson et al., 2006; LaBahn & Harich, 1997). One strategy has been to look for individual characteristics that predict the success of expatriate managers or international students, such as personality (Caligiuri, 2000), values (Kagan & Cohen, 1990), self-efficacy (Palthe, 2004), and interpersonal skills (Hechanova, Beehr, & Christiansen, 2003). Earley and Ang (2003) integrated many of these ideas in positing multiple dimensions of CQ, including knowledge, motivation, behavioral flexibility, and metacognitive awareness. Although there is now evidence that each of these dimensions affects some kinds of intercultural interactions (Ang & Van Dyne, 2008; Imai & Gelfand, 2010), theory about which dimensions are critical for which kinds of interactions is still developing. Furthermore, it is still unclear how these different dimensions of CQ interact with one another or combine into an aggregate construct (Thomas, 2010). Hence, rather than studying all CQ dimensions simultaneously, we focused our investigation on a single dimension—cultural metacognition—which Thomas and colleagues (2008) proposed to be a central linking mechanism among the various dimensions of CQ as it regulates cognition and behavior.

Metacognition may be the least obvious dimension of CQ, yet it follows a tradition of research emphasizing the importance of self-awareness and sensitivity toward others when adjusting to new environments (Mendenhall & Oddou, 1985). Cognitive psychologists typically characterize metacognition as thinking about thinking, comprising the processes of monitoring and adjusting one's thoughts and strategies as one learns new skills (Langer, 1989; Winn & Snyder, 1996). Expanding this line of theorizing, Ang et al. (2007) defined cultural metacognition as mental processes directed at acquiring, comprehending, and calibrating cultural knowledge. According to these researchers, cultural metacognition increases intercultural effectiveness by promoting (a) contextualized thinking (i.e., heightened sensitivity to the fact that individuals' motivations and behaviors are invariably shaped by the cultural contexts in which they are embedded) and (b) cognitive flexibility (i.e., discriminative use of mental schemas and behavioral scripts when interacting across cultures). Other scholars have also invoked ideas related to cultural metacognition in intercultural collaboration. For example, Johnson et al. (1996) emphasized the importance of self-awareness and awareness of others' responses in managing international collaborative alliances. Similarly, LaBahn and Harich (1997) emphasized the importance of cultural sensitivity in international collaborative ventures.

Cultural metacognition may be especially critical to collaborative relationships because of its effects on communication quality and ultimately intercultural trust. Individuals from different cultures are likely to interpret and represent the same problem in...
different ways, according to the cultural knowledge and beliefs that they respectively hold. Prior research argued that gaps in problem representation (Cronin & Weingart, 2007) inhibit collaboration because they increase misunderstanding and conflicts. Mere knowledge about the traditional practices of another culture, without accompanying metacognitive awareness, will not necessarily help in the collaborative work with a colleague from that culture. These preconceptions, if applied inaccurately, could even alienate associates from other cultures, making them feel stereotyped and decreasing trust. As the saying goes, “a little bit of knowledge is a dangerous thing.” Metacognitive awareness enables individuals to adjust their behavior to the particular audience, increasing rapport during interaction, thereby helping to build trust (Ang et al., 2007). A recent study by Gertsen and Saderberg (2011) on intercultural collaboration stories highlighted that the ability to adjust and learn during communication across cultures helps build mutual understanding, respect, and trust. High quality interpersonal communication and trust are especially critical for creative collaboration because unlike noncreative collaboration that involves merely sharing labor to implement preconceived ideas, partners in creative collaboration constantly grapple with uncertainty and new ideas and thus can easily feel vulnerable (Diehl & Stroebe, 1987; Diehl & Stroebe, 1991; Rubenson & Ronco, 1995). Effective interpersonal relationships smooth this difficult process. Initial evidence that cultural metacognition may promote intercultural creative collaboration comes from research by Crotty and Brett (2009). In a study of multicultural teams, these researchers found that team members with high cultural metacognition were more likely to report that their teams engaged in “fusion” teamwork, suggesting effective intercultural creative collaboration.

**Hypothesis H1.** Individuals' cultural metacognition is positively associated with effectiveness in their intercultural creative collaborations.

**Intervening processes: affect- vs. cognition-based trust**

We propose that the effect of cultural metacognition runs through affect-based trust, which arises proximally out of communication experiences. In a recent study, Liu, Chua, and Stahl (2010) found that feelings that one's communication with another person is clear, comfortable, and responsive are particularly predictive of success in intercultural as opposed to intracultural negotiations. This is consistent with the view that there are challenges distinctive to intercultural relationships that cultural metacognition may ameliorate. Our argument involves two more specific claims. First, the level of affect-based trust that one establishes in relationships to people of different cultures is a function of one's cultural metacognition. Second, affect-based trust in an intercultural relationship determines the success of creative collaboration.

Regarding the first claim, we argue that cultural metacognition affects managers' interaction by enabling them to adapt their styles appropriately, taking into account cultural differences yet not assuming more differences than truly exist. This adaptation creates the feeling of meshing—of being “on same wavelength”—with the other person, which is otherwise known as rapport. Rapport is a state of mutual positive interest and meaning that arises from communication experiences featuring coordination and synchrony of the expression of positive emotion (Bernieri, 1988; Tickle-Degnen & Rosenthal, 1990) and statements by the other that resonate with one's assumptions (Bernieri & Gillis, 1995; Gillis, Bernieri, & Wooten, 1995). Personal conversations, in which people share positive feelings, experiences, and values, are the seedbed of rapport and affect-based trust. However, with cultural differences, tensions can arise in personal conversation due to misunderstood references, misconstrued humor, and so forth. If an intercultural dyad has a member who can adapt to the other person, the dyad is more likely to have a resonant (“same wavelength”) conversation that results in mutual affect-based trust. To give a concrete example of this dynamic, when A has high cultural metacognition, he or she is likely to effectively adapt to B during conversations. In other words, A will avoid misunderstanding or offense and the strain and guardedness that ensues in intercultural interactions. This conversational meshing leads B to feel that A is on the same wavelength, A gets him or her, and A can be trusted at a more personal level. At the same time, A also feels in sync with B and develops affect-based trust. A's trust would be further reinforced as B shows signs of affect-based trust in his or her interaction in A such as empathy or personal interest. This process begins with A's effective adaption to B yet becomes a mutually reinforcing trust between the two parties.

Evidence also supports our second claim that affect-based trust enables creative collaboration. Recent research linking social network and creativity has emphasized that creativity is a social process (Burt, 2004; Perry-Smith, 2006) and that fluency and openness in the sharing of diverse and novel ideas is key to creative performance (Albrecht & Hall, 1991; Perry-Smith, 2006). Several studies manipulating whether or not dyads engaged in personalized communication found that this factor increases mutual positive affect and thereby increases collaborative approaches to resolving a conflict (Argyle, 1990; Drolet & Morris, 2000; Moore, Kurzberg, Thompson, & Morris, 1999). Chua, Morris, and Ingram (2010) found that affect-based trust is associated specifically with new idea sharing in managers' professional networks. Affect-based trust may be particularly important in intercultural relationships as it buffers the intercultural anxiety that often inhibits close cooperation (Stephan, Helms, & Haynes, 1995; Stephan & Stephan, 1985; Thomas, Bonieci, Vescio, Biernart, & Brown, 1996) and, specifically, the sharing of new ideas (Stephan, Stephan, Wenzel, & Cornelius, 1991). Related to anxiety, managers often feel strain and stress in intercultural relationships in the workplace (Takeuchi, Wang, & Marinova, 2005). Because it is often affective anxiety that impedes communication and cooperation in intercultural relationships, it stands to reason that affect-based trust would be a means of opening up communication and the flow of new ideas.

Additionally, affect-based trust helps address the challenges of conflict and misunderstanding that arise from cognitive gaps in problem representation common in intercultural relationships. Affect-based trust can increase the motivation for the parties involved to carefully listen to and understand the other's alternative perspectives, as opposed to outright dismissing them. When individuals understand and appreciate perspectives that are different from their own, they can better manage the associated frictions, engage in constructive debate, and harness the inherent differences to generate creative solutions to problems, processes sometimes referred to as “creative abrasion” by management scholars (Leonard & Swap, 1999; Nonaka, 1994). In sum, we posit that because affect-based trust opens up the conduit for frank two-way communication of new ideas and motivates individuals to better understand diverse perspectives, it enables creative collaboration between culturally different individuals.

**Hypothesis H2.** The relationship between individuals' cultural metacognition and effectiveness in their intercultural creative collaborations is mediated by affect-based trust.

An alternative account centers on predicting that cognition-based trust is a mechanism. That is, individuals with low cultural metacognition may rely on pejorative stereotypes about cultural out-groups. They might have simplistic routines or templates for engaging people of other cultures which limit their interactions and hence underestimate the competence and reliability of their.
collaborators from other cultures. Although low metacognitive CQ could lower cognition-based trust, individuals’ perceptions of colleagues’ reliability and competence probably does not hinge as much on the quality of their interactions as does their affective feelings toward the colleagues. In the professional world, and even in the university, one’s perceptions of others’ competence and reliability comes largely from their reputations and track records. They do not depend as much on one’s first-hand interactions as do one’s feelings of affect-based trust.

The second part of this alternative account involving a cognition-based trust mechanism would be that lower judgments of colleagues’ competence and reliability would interfere with creative collaboration. This part is hard to dispute. Outside of the cultural psychology literature, studies of team interaction highlight the importance of cognitive perceptions of colleagues’ capacities as opposed to affective bonds. Team performance on well-structured problems like puzzles is fostered by group task training, which affords accurate perceptions of others’ competencies (transactive memory), and not by team-building training, which instills affective bonds (Moreland, Argote, & Krishnan, 1996; Moreland & Myasnikov, 2000). More generally, negative expectations of competence and reliability in culturally different others would reduce their attractiveness as exchange partners or “sounding boards” for new ideas. Low confidence in the competence of the other would also decrease one’s willingness to listen to alternative ideas and perspectives from that person. These effects would in turn dampen creative collaboration. In sum, it is important to test this alternative account predicting that cognition-based trust is the mechanism for the effect of cultural metacognition on intercultural creative collaboration.

**Empirical approach**

Our hypotheses specify how an individual level construct (cultural metacognition) gives rise to an event that occurs in intercultural relationships (creative collaboration). This event is determined by two people and perceived by both of them; it can be measured with either of these perceptions or through an objective scoring of their work product. Across our studies we use all of these measures, although not all of them in every study. Our approach is to begin with a test of the link between the independent variable (cultural metacognition) and dependent variable (intercultural creative collaboration). Then we progressively unpack the causal chain by examining intervening mechanisms and limiting conditions. We did so using three different research methods that involve different ways of operationalizing the constructs.

Study 1 uses a multi-rater assessment to test whether a focal manager’s cultural metacognition predicts his or her intercultural creative collaboration success as observed by associates from other cultures. By tapping other-culture associates for each of our focal respondents we seek to demonstrate that the effects of cultural metacognition on intercultural creative collaboration are not merely imagined by the focal managers but rather are real and thus apparent to others. Study 2 then tests the boundaries of this effect by looking across the major relationships of a focal manager. Using an egocentric network survey, we ask each manager about the major relationships in his or her professional network, only at the end asking for the cultural background of each associate so that intra- and inter-cultural relationships can be compared. Trust and sharing of new ideas (a behavior inherent to creative collaboration) are conceptualized as interpersonal processes yet operationalized as perceptions from the focal manager’s perspective. This approach of assessing interpersonal level variables from one member of the pair is common in organizational research, such as negotiations research (Overbeck, Neale, & Govan, 2010) and relationship research (Kenny, 1996). A strength of Study 2 is external validity—it captures the most important relationships of these manager’s professional networks. We seek to demonstrate that the effects of cultural metacognition hold for relationships to different-culture alters but not same-culture alters.

The final study switches to the method of laboratory experiments, gaining internal validity. It examines the hypotheses by considering cultural metacognition on both sides of the intercultural pair concurrently. Because we do not have a priori predictions on how two individuals with differing levels of cultural metacognition would interact, we conducted a pilot study to explore the dynamics. A shift in this study is our analysis of the hypothesized constructs at the dyadic level by considering the maximum, minimum, and average scores of the variables in each dyad. This approach is consistent with recommendations in the groups literature that considers different conceptualization of group constructs such as average, minimum, maximum, and variance (Barrick, Stewart, Neubert, & Mount, 1998; Brannick, Salas, & Prince, 1997). Drawing on findings from the pilot study, Study 3 then provides a more formal test of our hypotheses with all constructs analyzed at the dyadic level.

This combination of methods with complementary strengths provides a stronger test of the validity of the hypotheses than would be possible with one method alone.

**Study 1**

**Participants and procedures**

A total of 43 middle-level managers (81% male, mean age 38) attending an executive MBA course at a large west coast US university participated in this study. Of these, 51% were European-American, 35% East- or South Asian, and the rest were of other cultural backgrounds (e.g., European, Middle Eastern, etc.). These participants rated themselves on the cultural metacognition measures. Our dependent measure—managers’ creative collaboration in intercultural relationships—was rated by individuals on the other end of those relationships, namely, people of different cultural backgrounds who had worked with the focal managers. Our focus is to get an overall assessment of each manager’s creativity-related effectiveness in their range of dyadic working relationships with coworkers of other cultures.

As part of their course requirement, these participants were asked to nominate up to 10 people of different cultural backgrounds with whom they had previously worked professionally to provide them with feedback. We told participants that they would receive only aggregate feedback and would never learn which of their observers had filed reports. We checked that these nominated “observers” reported different cultural backgrounds than the focal manager. The observers included identified peers, bosses, and subordinates. On average, 4.37 observers responded for each focal manager, resulting in a total of 188 data points. Each participant was rated by multiple observers, but these observers are unique to each participant and do not rate other participants. Observers were asked to rate the participant on an array of measures related to leadership development, including items tapping creative collaboration. Rather than asking observers narrowly about their own personal experiences with the focal manager, we asked observers for their general impressions based on what they have experienced and observed, in order to more broadly capture the manager’s tendencies in intercultural interactions.

**Key measures**

**Cultural metacognition**

Participants rated their own cultural metacognition using a six-item metacognitive CQ scale developed by Van Dyne and
colleagues (Van Dyne et al., 2011). These items tap (a) cultural awareness (e.g., “I am aware of how to use my cultural knowledge when interacting with people from different cultures”); (b) adjustment during intercultural interactions (“I adjust my cultural knowledge while interacting with people from a new or an unfamiliar culture”); and (c) planning before intercultural interactions (e.g., “I develop action plans for interacting with people from a different culture”). Cronbach’s alpha for this scale is 0.88 for the current sample.

**Intercultural creative collaboration**

We used third-party observations to assess participants’ behaviors in intercultural creative collaboration. Specifically, the dependent measures came from peers who were of different cultural backgrounds than the participants. These observers responded to two items designed to assess participants’ effectiveness in interacting with people of other cultures: (a) “This person typically proposes win-win solutions when people from different cultural backgrounds have divergent ideas” and (b) “This person’s working relationships with people of other cultural backgrounds help this person and the others do creative, innovative work.” Respondents used a 7-point scale (1 = not at all, 7 = to a great extent). Correlation between these two items was .57. The rwg for the scale is .78, suggesting adequate inter-rater agreement on the outcome variable. We averaged these two items to form our dependent variable.

**Control variables**

Because prior multicultural experience has been found to influence creative performance (Leung et al., 2008; Maddux & Galinsky, 2009), we controlled for related measures. Specifically, we assessed the number of languages the participants spoke and the number of countries where they have lived (“How many different countries have you lived in [for at least 6 months] over your lifetime?”) and visited in the previous year (“How many different countries have you visited during the last year?”). We measured these two variables separately because Maddux and Galinsky (2009) found that living overseas for extended periods but not visiting foreign countries predicted creativity. Lastly, we also assessed the degree of participants’ previous experiences in interacting with people from different cultures and countries using these items “your overall experience interacting with people who have different cultural backgrounds” and “your overall experience interacting with people from other countries.” These items were rated on a 5-point scale ranging from 1 = no experience to 5 = very experienced. We combined these two items (correlated at .81) into a single indicator called “past foreign experiences.” All responses on the control variables were reported by the participants themselves.

**Analyses and results**

Our data involved hierarchically nested variables given that up to 10 observers are nested within a particular respondent. A methodological concern therefore was the non-independence of observations (Klein, Dansereau, & Hall, 1994). To address this data non-independence issue, we used the random-effects regression model (also known as the hierarchical linear model) to control for the influence of a given participant on multiple dyadic observations (Hausman, Hall, & Griliches, 1984; Hoffman, Griffin, & Gavin, 2000). We chose the random-effects model because cultural metacognition is a participant-level variable; moreover, this model also allows estimates for other substantively interesting aggregate participant-level variables such as international experience and foreign language ability.

**Table 1** shows the descriptive statistics and correlations among the key variables. **Table 2** reports the results from the hierarchical linear model analyses of observers’ rating of participants’ intercultural innovation effectiveness. Model 1 contains the control variables whereas model 2 adds the predictor of self-reported cultural metacognition. Results indicate that cultural metacognition has a positive effect (b = .19, p < .05) on observers’ ratings of participants’ ability to engage in intercultural creativity-related work, controlling for prior multicultural experience and foreign language ability. Thus, there is support for hypothesis H1.

**Discussion**

A key contribution of Study 1 is disambiguating cultural metacognition from individual differences in experience as we controlled for dimensions of international and multicultural experience. While cultural metacognition may be in part a consequence of such experiences, we show that it is not simply a proxy for them—cultural metacognition predicts our effects even when levels of these experiences are controlled. Another important

contribution is the use of independent ratings by coworkers from other cultures which provides further assurance that the findings reflect real (rather than imagined) collaborative success. In our next study, we aim to unpack the trust mechanism by measuring both affect- and cognition-based trust and testing their effects. Additionally, we go beyond the general assessment of collaboration effectiveness to measure a specific behavior of creative collaboration—new idea sharing (Albrecht & Hall, 1991; Hennessy & Amabile, 2010; Taggar, 2002).

**Study 2**

**Participants and procedures**

We surveyed 60 managers attending an executive MBA course in the US (77% male, mean age 35). Of these managers, 66% were European-Americans, 19% East- or South-Asians, and the rest were of other cultural backgrounds (e.g., African-American, European, Middle Eastern, etc.). All had substantial careers as professionals, most as managers in private sector companies, with high-tech firms most commonly represented.

As part of their course requirement, participants completed a social network survey that allowed them to list up to 24 contacts (alters) they considered important members of their professional networks. Specifically, we asked participants to “list anyone that you feel is a significant part of your professional network. One way to identify these people is to go through your address book, and ask ‘is this person significant in my professional network?’ If you have more than 24 significant contacts, list the most significant 24.” This method of surveying our participants’ networks allowed us to identify key network members with whom they were likely to collaborate at work and yet not cue participants about the nature of our hypotheses.

On average, participants listed 22 contacts, resulting in a total of 1219 dyadic participant-alter observations. For each alter listed, the participants provided details regarding their relationship (e.g., frequency of interaction and length of relationship). Also, they indicated whether the basic content of their tie included emotional, economic, task advice, and career advice exchange, which are standard categories in the study of professional networks. Our key criterion variable of sharing new ideas was measured after these relationship questions were completed. Participants finally indicated whether or not the listed contacts were themselves connected.

**Key measures**

**Cultural metacognition**

Several weeks prior to the network survey, participants completed the Ang et al. (2007) metacognitive CQ subscale. The four items include “I am conscious of the cultural knowledge I use when interacting with people from different cultural backgrounds,” “I am conscious of the cultural knowledge I apply to cross-cultural interactions,” “I adjust my cultural knowledge as I interact with people from a culture that is unfamiliar to me,” and “I check the accuracy of my cultural knowledge as I interact with people from different cultures.” Cronbach’s alpha for this sample is .78.

**Inter- vs. intra-cultural relationships**

We asked participants to indicate the cultural background of each listed contact. The categories, designed to fit the population, were European American, African-American, and Asian-American, as well as European, Asian, Middle Eastern, Latino, and other. We then matched the cultural background of the participants with each indicated response to derive a dummy variable, coded “1” if participant and alter’s cultural backgrounds are different, “0” if otherwise.

**Creative collaboration – sharing of new ideas**

We operationalize creative collaboration in terms of a critical specific behavior – new ideas sharing. After the questions regarding social networks, participants were asked a question that focused on the exchange of new ideas and information with each contact. We measured the likelihood that participants discuss new ideas at work with each alter through the item: “How likely are you to share new insights or information with this person?” Responses were rated on a 5-point scale: 1 (not at all) to 5 (to a great extent). We used a single-item measure to minimize tedium in completing the survey because participants had to answer the same question for every contact they listed. Single-item measures are commonly used in network research for this reason (Ferrin, Dirks, & Shah, 2006; Marsden, 1990; Umphress, Labianca, Brass, Kass, & Scholten, 2003). Prior research suggests that single-item measures are acceptable when it is impractical to use multi-item scales due to situational constraints (Wanous, Reichers, & Hudy, 1997).

We queried participants’ practice of sharing new ideas, as opposed to their retrospective recall of sharing new ideas. This approach avoids some problems related to memory biases. Research on memory for relationships suggests that people can accurately recall tendencies (e.g., how often on average one talks to someone per week) but not specific interactions (Stafford, Burggraf, & Sharkey, 1987). In particular, the sharing of an idea that was new at the time might not be remembered as so upon retrospection, when the idea has become so familiar it seems obvious. Our approach of measuring idea sharing as a habitual practice skirts these problems.

**Trust**

We adapted measures of affect- and cognition-based trust from high factor-loading items (above .80) in McAllister’s (1995) study. For affect-based trust, participants indicated on a 5-point scale (1 = not at all, 5 = to a great extent) the extent to which they felt comfortable going to each listed alter to share (a) their personal problems and difficulties and (b) their hopes and dreams. These items capture the extent to which participants are willing to make themselves vulnerable to their network alters by disclosing personal information. For cognition-based trust, participants indicated on the same 5-point scale the extent to which they could rely on each listed alter to (a) complete a task that alter has agreed to do and (b) have the knowledge and competence for getting tasks done. The correlation for the two affect-based trust items is .81, whereas that for the two cognition-based trust items is .65.

We conducted multilevel confirmatory factor analyses (CFA) using structural equation modeling (LISREL 8.80) to ensure that the three outcome variables (cognition- and affect-based trust, and new idea sharing) are distinct. Results indicate that a three-factor model where new ideas sharing, cognition-based trust, and affect-based trust items load into respective separate factors has a better fit to the data ($\chi^2 = 65.58$, df = 10, RMSEA = 0.09) than a one-factor model ($\chi^2 = 467.17$, df = 10, RMSEA = 0.28) or a two-factor model with items for affect-based trust and new idea sharing loading onto the same factor ($\chi^2 = 118.55$, df = 11, RMSEA = 0.13).

**Control variables**

Participants’ tendency to share new ideas with alters may be influenced by the extent of exposure to people of different cultures. To control for cultural diversity in professional networks, we measured the degree of cultural diversity in participants’ networks using Blau’s (1977) heterogeneity index. A high score on this index
indicates variability in the cultural backgrounds among network members. We also controlled for other attributes that could influence interpersonal trust and hence the sharing of new ideas. Specifically, we controlled for the size of participants’ network (number of alters) because prior research suggests that people have limited capacity in maintaining relationships (Granovetter, 1973).

We also controlled for the degree to which alters are embedded (how connected a given alter is to the other alters in the participant’s network) and the content of the relationship between participant and alter (e.g., friendship, economic exchange) because past research found that these factors differentially influence cognition- and affect-based trust (see Chua, Ingram, and Morris (2008) for details). Finally, we controlled for the job function that the participant was in given that different types of jobs may require different levels of creative collaborations. We coded the participant’s job function based on eight categories: (1) finance/accounting, (2) sales/marketing, (3) operations, (4) general management, (5) technical, (6) business development, (7) research & development, and (8) other. Dummy coding for these categories were used and entered as controls in the regression analyses.

Analyses and results

Data non-independence is an issue with our dataset given that up to 24 dyadic relationships are nested within a single respondent. As in Study 1, we used random-effects models for our analyses. Although our analysis focus was on the dyadic relationships, the random-effects model allows for estimation and control of important participant-alter-level variables such as network size and the degree of cultural diversity in participants’ networks.

Table 3 shows the descriptive statistics and correlations among key variables. Table 4 reports the results from hierarchical linear model analyses of participants’ networks. Model 1 contains the control variables and the key predictors. Model 2 adds the interaction effect between participant-alter cultural difference and cultural metacognition. We found a significant interaction effect (b = .21, p < .01) such that participants’ cultural metacognition predicts new idea sharing with alters of different cultural background (b = .21, p = .05) but not with alters of the same cultural background (b = -.07, n.s.). This interaction is illustrated in Fig. 1a.

Models 3 and 4 show results for affect-based trust. We observed the same pattern of results as that for sharing new ideas. In model 3, cultural metacognition and participant-alter cultural difference did not have any significant direct effect on affect-based trust. In model 4, the interaction involving these two variables is significant (b = .26, p < .01) such that a participant’s cultural metacognition predicts his or her affect-based trust in alters of different cultural background (b = .29, p < .05) but not in alters of the same cultural background (b = .00, n.s.). As may be seen in Fig. 1b, this interaction effect has the same form as that for new idea sharing. There is a deficit in affect-based trust for low metacognitive CQ managers in their intracultural ties compared to intracultural ties, or compared to high metacognitive CQ managers in either type of ties. Models 5 and 6 show results for cognition-based trust. The key predictors and their interaction exert no significant effect on this type of trust.

Next, we examined both types of trust as mediators. Because the effect of cultural metacognition on new idea sharing occurs only when alters are culturally different from the participant, we focused on this subset of alters. Table 5 presents the mediation results. Following the Baron and Kenny (1986) procedure for mediation analyses, we first show in model 1 that cultural metacognition has a positive effect on affect-based trust (b = -.29, p < .05). Model 2 indicates that cultural metacognition had no effect on cognition-based trust (b = -.08, p > .10), ruling out the alternative explanation that cognition-based trust is a mediator. Model 3 shows the direct effect of cultural metacognition on likelihood to share new ideas (b = .21, p < .05). When we added affect-based trust in the analyses (model 4), the effect of cultural metacognition completely disappeared suggesting a mediation effect. The effect of affect-based trust on the dependent variable of idea sharing remains significant. For completeness, models 5 and 6 show effects of adding cognition-based trust and both types of trust. These two models show that controlling for cognition-based trust, adding affect-based trust causes the effect of cultural metacognition to disappear. Bootstrapping mediation analyses (Preacher & Hayes, 2004; Shrout & Bolger, 2002) using 5000 iterations with 95% confidence interval (CI) indicated that the indirect effect through affect-based trust as mediator is significant (95% CI = 0.01–0.17; bias-corrected confidence interval excludes zero), but that for cognition-based

Note: p < .05.
trust is not (95% CI = −0.10 to 0.01). In sum, these results suggest that with low cultural metacognition, managers’ reduced likelihood to share new ideas is mediated by affect-based trust but not cognition-based trust.

Discussion

Study 2 demonstrated that managers with lower cultural metacognition are less likely to have developed affect-based trust in their intercultural relationships and are thereby less likely to share new ideas in these relationships. A strength of the network survey method in Study 2 is specifying the scope of the effect: results showed that the deficits in trust and creativity-related communications associated with lower cultural metacognition appear solely in intercultural relationships, not in intracultural relationships. This finding suggests that cultural metacognition is not simply a proxy for domain general traits such as openness or creativity, but a construct specifically relevant to intercultural interactions.

Fig. 1a. Creative collaboration (participant’s likelihood to share new ideas with alter) as a function of the interaction between cultural metacognition and participant-alter cultural difference (Study 2).

Fig. 1b. Participant’s affect-based trust in alter as a function of the interaction between cultural metacognition and participant-alter cultural difference (Study 2).
Although the egocentric network survey in Study 2 allows assessment of the mediating and dependent variables with respect to all of the important relationships in a manager’s professional life, it has the limitation of relying on the respondent’s self-report. Relatedly, all the responses in Study 2 were collected from the same source (i.e., the respondent). Although the key predictor of cultural metacognition was administered separately from the rest of the survey at a different point in time, ameliorating some concerns associated with common method bias (Podsakoff, Mackenzie, Lee, & Podsakoff, 2003), it would be valuable to replicate the key effects with independent and dependent variables collected from separate sources and at different points in time. In the next study, we do so.

**Study 3**

Our prior studies have surveyed executives and their associates about the important professional relationships in their career. The evidence these studies have provided for the link between cultural metacognition and creative collaboration is high in external validity; however, the purely associational nature of survey methods means that the evidence is lower in internal validity. To know whether cultural metacognition causes affect-based trust and creative collaboration, rather than the causality flowing in the opposite direction, it is necessary to investigate the manifestation of trust in an interaction between people who do not already have a close working relationship.

A pilot study examined whether the relationships among cultural metacognition, trust, and creative collaboration hold in dyads assembled for a task who have no prior working relationship. The objective of this pilot study is to explore a method to study dyadic intercultural creative collaboration, helping to set the stage for Study 3. Seventy-six MBA students (58% male, mean age 28.6) were assigned into dyads for an in-class negotiation exercise. These 38 dyads were constructed such that each consisted of two students with different cultural backgrounds. These students did not know each other well prior to this exercise—a pre-negotiation survey found that students reported a low interaction frequency with their assigned partner both socially (average = 1.67) and professionally (average = 1.37) on a 7-point frequency scale (1 = never, 4 = to two times a month, 7 = daily). Following a 5-min ice-breaker where students talked about their experiences at the university, they were given 20 min to complete the negotiation. Students then completed a post-negotiation survey that, among other things, tapped their degree of trust and assessment on whether their partner would be a good partner for future creative collaboration, our criterion variable. The key measures in this pilot study are (a) cultural metacognition—measured using the same six-item scale as in Study 1; Cronbach’s alpha for this scale is .88 for the current sample; (b) intercultural trust—measured with the question “Did the negotiation make you trust your counterpart? (1 = not at all, 4 = to some extent, 7 = to a great extent)” and (c) perception of the other as an effective partner for creative collaboration—measured by the question: “Based on your interaction with your counterpart in this negotiation exercise, to what extent is he or she a good partner to work with on future projects that require considerable innovation and creativity? (1 = not at all, 4 = to some extent, 7 = to a great extent).”

We analyzed our data at the dyadic level, computing dyad-level cultural metacognition, trust, and creative collaboration by taking the average of the two partners’ ratings on these variables. We found that dyad-level cultural metacognition has a positive association with perceptions that the counterpart is an effective partner for creative collaboration (b = .52, p < .05). When trust was included in our analyses, this association disappeared (b = .31, p = .14), suggesting a mediation effect. Using 5000 bootstrap re-samples with a 95% confidence interval in our analyses, we found a significant mediation effect—bias-corrected confidence interval for the indirect effect does not include zero (95% CI = 0.07–0.50). Average cultural metacognition had a positive relationship with trust (b = .68, t = 2.19, p < .05), which in turn had a positive relationship with the dependent variable (b = .30, t = 2.90, p < .01).

We further analyzed the dyad composition to better understand if it was the higher or lower of the dyads’ cultural metacognition that drove this pattern of result. Thus, instead of using the average level of the partners’ cultural metacognition ratings, we created two variables to denote the higher and the lower value of this variable in each dyad. We found that it was the person with the higher cultural metacognition in the dyad that is driving the relationship. Specifically, the maximum cultural metacognition in a dyad has a significant positive relationship with creative collaboration (b = .42, p = .01). When trust is included in the analyses, the effect of cultural metacognition on creative collaboration disappeared (b = .19, p = .29). Trust significantly predicts creative collaboration (b = .29, p < .05). Mediation analyses indicated significant mediation—bias corrected confidence interval for the indirect effect does not include zero (95% CI = 0.07–0.50). The minimum cultural metacognition in a dyad did not have a significant relationship with creative collaboration (b = .21, p = .26).

The pilot experiment adds to the prior evidence by measuring trust in stranger dyads. Importantly, it shows that a dyad needs at least one person high in cultural metacognition to bridge the gap in intercultural creative collaboration. This pilot experiment, however, did not have any concrete measure of creative collaboration, relying on self-report of whether the other would be a good partner for future creative collaboration. Additionally, analyses using non-experimental data risk producing biased estimates of mediation effects because unobserved variables may cause the error terms of the mediator and outcome variables to co-vary (Bullock, Green, & Ha, 2010; Spencer, Zanna, & Fong, 2005). Various scholars have recommended using an experimental approach wherein the mechanism is manipulated to lend further credence to claims of mediation effects (Bullock et al., 2010). We next conducted a laboratory experiment to address these concerns. Rather than manipulating the mediator directly, we manipulated the context that influences affect-based trust, our mediator, to more incisively demonstrate the effect of this variable. We also used third-party expert assessments to gauge creativity of prod-
ucts jointly created by dyads comprising individuals from different cultures.

Participants and procedures

We recruited 236 students (45% male, mean age 21.3) from a large east coast university to complete a series of tasks. Upon arriving at our laboratory, participants independently completed a battery of individual differences questionnaires, including a measure of cultural metacognition. This was followed by a filler survey for an unrelated study and an individual task. In this task, participants were given a list of ingredients from different cultures (e.g., American, Chinese, Indian, Thai, etc.) and asked to generate a recipe for a new chicken dish for a soon-to-open restaurant. This task was adopted from one used by Cheng, Sanchez-Burks, and Lee (2008).

Next, we randomly matched each participant with another participant who is of a different cultural background, based on their self-report cultural backgrounds (including European-Americans, African-Americans, Asian-Americans, and international students from various countries). We checked with the participants in each dyad to ensure that they had no prior relationships. These dyads were then assigned into one of two experimental conditions (see below). Participants were told they were about to do a collaborative task, but we gave details of the joint task only after the experimental manipulation. After the manipulation, participants learned that the joint task was to collaboratively create a new chicken dish recipe. This joint task represents a scenario that an entrepreneurial team might face and that would reward creative collaboration. The joint recipe had to be different from the individual recipes created earlier. In both individual and joint tasks, we told participants that their recipes had to be creative—defined as “new, delicious, and popular with potential customers.” Upon completing the joint task, participants independently completed a post-task survey on their collaboration experience.

Manipulation

About half of the 118 dyads (62) were randomly assigned to the “personal conversation” condition, and the rest to the “no-conversation” condition. In the “personal conversation” condition, similar to the paradigm used in the pilot study, participants in the dyad were told to have a personal conversation before the work task began. The procedure required participants to share with each other important and meaningful personal moments that they had experienced at the university which have shaped their feelings toward the university community. Participants were cautioned by the experimenter to discuss only this topic and nothing else. In the “no-conversation” condition, participants were simply introduced before receiving instructions for the problem solving task. This condition was designed to go beyond demonstration of the associative mediation effects in the prior studies and examine what happens when the preconditions for affect-based trust, the key mechanism in our thesis, are absent. In sum, we were allowing participants to build affect-based trust prior to the joint task in one condition but not the other. Dyads who held an initial personal conversation should develop affect-based trust to varying degrees, one condition but not the other. Dyads who held an initial personal conversation should develop affect-based trust to varying degrees, one condition but not the other. Dyads who held an initial personal conversation should develop affect-based trust to varying degrees, one condition but not the other. Dyads who held an initial personal conversation should develop affect-based trust to varying degrees, one condition but not the other. Dyads who held an initial personal conversation should develop affect-based trust to varying degrees, one condition but not the other. Dyads who held an initial personal conversation should develop affect-based trust to varying degrees, one condition but not the other.

Evaluation of creativity

We measured both cognition- and affect-based trust using three items each (adapted from McAllister, 1995) right before the participants began the joint task. For cognition-based trust (Cronbach’s alpha = 0.89), participants rated the extent that they could rely on their assigned partners to (a) complete a task that they had agree to do, (b) have the knowledge and competence for getting tasks done, and (c) approach their work with dedication and professionalism. For affect-based trust (Cronbach’s alpha = 0.82), participants rated the extent that they felt comfortable going to their partners to (a) share their personal problems and difficulties, (b) share their hopes and dreams for the future, and (c) obtain constructive and caring feedback about problems they had. We aggregated the two partners’ responses to derive dyad level measures for each type of trust.

Creative collaboration

We assessed effectiveness in intercultural creative collaboration with three measures. First, participants rated their counterparts using a 7-point scale to the extent that they were good partners for creative work. We used the following three items: (a) “How forthcoming is your partner in sharing his or her ideas with you?” and (b) “How open is your partner in sharing information that he or she knows with you?”; and (c) “To what extent is he or she a good partner to work with on projects that require considerable innovation and creativity?” Cronbach’s alpha for this scale is 0.92.

Second, we measured participants’ assessment of information and idea exchange during the joint task. The items were (a) “How forthcoming is your partner in sharing his or her ideas with you?” and (b) “How open is your partner in sharing information that he or she knows with you?”; and (c) “To what extent is he or she a good partner to work with on projects that require considerable innovation and creativity?” Cronbach’s alpha for this scale is 0.92.

Our third measure involved third-party ratings of the joint recipes created by dyads. Two expert judges with culinary experience independently evaluated the recipes on five dimensions (delicious, popular, novel, unique, and creative). Judges were told that a “creative” dish is one that is both new and tasty. Overall, this performance measure captured both the usefulness and novelty aspects of creativity. Cronbach’s alpha for this scale is 0.75 and inter-rater reliability is 0.64, so we aggregated the items across the two judges to create a composite score for joint creative performance. We also evaluated the individually created recipes in the same way.

Manipulation checks

Analysis of variance indicated that, controlling for dyad level cognition-based trust, dyad level affect-based trust was higher in the personal conversation condition than in the no-conversation conditions.

---

2 Any form of communication, even if it was about a non-personal topic like a current event, could induce affect-based trust if the participants discovered common personal attitudes, aspirations, and values during the conversation (Peters & Kashima, 2007; Pullin, 2010). 2 Any form of communication, even if it was about a non-personal topic like a current event, could induce affect-based trust if the participants discovered common personal attitudes, aspirations, and values during the conversation (Peters & Kashima, 2007; Pullin, 2010). Thus, to examine what happens when there is no opportunity to
the two conditions have comparable prior creative ability on the higher of the individual creative performance in a dyad (partners for creative work) was positively associated with the (but not idea sharing or perceptions of counterparts as effective > .10). Further analyses found that joint creative performance in each dyad. Results indicate that cultural metacognition manipulation had no main effect on the dependent variables two cultural metacognition scores. Model 1 shows that conversational effects, we tested our hypotheses with this variable. For each dyad, cultural metacognition in a dyad that primarily accounted for our proposed ef- fects, we tested our hypotheses with this variable. For each dyad, we derive a new variable that takes the value of the higher of the two cultural metacognition scores. Model 1 shows that conversational manipulation had no main effect on the dependent variables (p > .10). Model 2 adds the higher of the two cultural metacognition scores in each dyad. Results indicate that cultural metacognition had a significant main effect on joint creative outcome (b = 1.4, p < .05) but not the other two variables. Model 3 adds the interaction term between cultural metacognition and the conversation manipulation, revealing significant interaction effects for all three dependent variables. The pattern of interaction is such that cul- tural metacognition had positive effect on the creative collaboration anticipated to build affect-based trust. This finding is consistent with prior results from moderated mediation analyses, all the indirect effects are significant with the 95% CI excluding zero. Cognitive-based trust was not a viable mediator—when this variable was added in our analyses, all the effects of cultural metacognition on the outcome variables remained intact. None of these above reported mediation effects surfaced when we analyzed only data in the no-conversation condition.

Discussion

This study shows that when working with a stranger from a different culture on a task that rewards creative collaboration, high cultural metacognition in one of the two individuals gives the dyad the potential for affect-based trust and creativity. This potential, however, is only realized if the partners have a personal conversa- tion to build affect-based trust. This finding is consistent with prior findings that rapport develops between strangers when they are asked to have a personal conversation about feelings they have in common (e.g., Drolet & Morris, 2000). A key feature of Study 3 is the experimental manipulation of conditions that facilitate the mediating mechanism. This experimental approach to mediation conversation vs. no-conversation) “moderates” the effect of cul- tural metacognition on affect-based trust, which in turn predicts the outcome variables related to intercultural creative collaboration. Using SPSS macros specified by Preacher, Rucker, and Hayes (2007), we tested the conditional indirect effects of cultural meta- cognition on the dependent variables for each level of the manip- ulation using the bootstrapping approach with 5000 iterations. Results indicate that interaction effects between the manipulation and cultural metacognition were significant for all three outcome variables and affect-based trust (p < .05). The indirect effects in the personal conversation condition were significant in that the 95% bias-corrected confidence interval for these effects did not include zero (joint creativity performance: CI = 0.01–0.12; perception of other as effective partner for creative work: CI = 0.01–0.18; new idea and information sharing in dyad: CI = 0.01–0.13). Conversely, the indirect effects in the no-conversation condition were all non-significant in that the 95% bias-corrected confidence interval for these effects included zero (joint creativity perfor- mance: CI = −0.07 to 0.06; perception of other as effective partner for creative work: CI = −0.06 to 0.05; new idea and information sharing in dyad: CI = −0.06 to 0.05). Further bootstrapping tests with 5000 re-sampling to compare the two sets of indirect effects indicated that these effects are significantly different (95% bias-corrected CI excluded zero for all three outcome variables: joint creativity performance: CI = 0.01–0.22; perception of other as effective partner for creative work: CI = 0.01–0.19; new idea and information sharing in dyad: CI = 0.01–0.16).

provides further confidence for our proposed mediation argument. Additionally, this study adds to prior studies in this research by providing empirical evidence involving objective evaluation of creative outcomes, rather than merely self- or peer-reports.

**General discussion**

Our research demonstrates that variation across individuals in cultural metacognition determines success in intercultural creative collaboration. Four studies collectively provide compelling evidence that individuals high in cultural metacognition are more effective in intercultural creative collaboration, in part because they develop higher affect-based trust in their intercultural relationships.

**Theoretical implications**

This research makes several theoretical contributions. First, cultural metacognition appears linked to a certain type of trust. Affect-based trust, but not cognition-based trust, is positively associated with cultural metacognition. Why not cognition-based trust (i.e., individuals’ expectations of the other’s competence and reliability)? Most likely, these expectations are less contingent on one’s personal interaction with a given colleague and more on objective indicators, such as the other’s observable accomplishments and institutional affiliation (see Morris, 2011). Individuals with low cultural metacognition may have just as much cognition-based trust in their intercultural ties as do high cultural metacognition individuals, but they lack the affect-based trust that arises out of personal experiences of meshing well through mindful intercultural interactions. Another explanation for the affective pathway from cultural metacognition involves people’s motivation to adapt and modify their cognitive schemas during intercultural interactions. This motivation grows through affect-based trust to the extent that people are more motivated to adjust their schemas if they feel stronger emotional bonds with their partners of different cultures and genuinely want their collaborative relationship to work.³

Second, we extend existing research on culture and creativity (Goncalo & Staw, 2006; Leung et al., 2008). Several areas of psychology and organizational research have linked cultural diversity and creativity. At the individual level, performance on creativity tasks is higher for people with extended life experience in diverse cultures (Leung et al., 2008; Maddux & Galinsky, 2009). At the group level, cultural diversity is associated with increased creative problem solving, provided there is enough time to work through miscommunications and conflicts (Giambatista & Bhattu, 2010; Hackman, 1990; Swann, Kwan, Polzer, & Milton, 2003). Our research looks at the dyad level to explore creative collaboration between people of different cultures. Our findings join emerging psychological research (Cheng et al., 2008) in emphasizing the role of individual differences in harnessing the power of multiculturalism for creativity. Cheng and colleagues found that only bicultural individuals with integrated cultural identities tend to be creative on tasks calling for knowledge that draws on both identities; we show that individuals who are low in cultural metacognition are less likely to share new ideas in cross-cultural relationships and succeed in intercultural creative work. Hence, merely having access to multiple cultural knowledge sources seems insufficient for creativity and its related processes to flourish. Similarly, having multiple cognitive structures does not necessarily mean that one is able to recombine them creatively to suit new cultural challenges. Only individuals with the attributes needed for connecting the multiple knowledge sources or cognitive structures gain an innovation advantage. Our finding therefore extends a growing area of organizational research that suggests that innovation can arise from having diverse social network ties in combination with a communication process that enables ideas to come together (Burt, 2004; Hargadon & Bechky, 2006).

Third, our research expands existing creativity research by focusing squarely on intercultural creative collaboration. Over the past decades, researchers have produced voluminous research on individual and group creativity, documenting effects of various antecedents (e.g., intrinsic motivation and team diversity, etc.) and contextual factors (e.g., leadership style, network structures, and organizational climate, etc.) (George, 2007). Surprisingly little research has been conducted on creativity at the dyadic level. In addition, it is only in recent years that scholars have begun to explore the effects of culture on creativity (De Dreu, 2010; Leung et al., 2008; Maddux & Galinsky, 2009; Mok & Morris, 2010; Morris & Leung, 2010). Given that global problems increasingly call for intercultural collaboration, it is important that researchers explicitly investigate antecedents and barriers to effective intercultural creative work. Our research represents an original effort in this direction.

Fourth, our research contributes to the growing body of research on CQ. Recent research by Imai and Gelfand (2010) found that in the context of intercultural negotiations, only minimum overall CQ and motivational CQ (drive and confidence to engage culturally different others) predicted integrative behaviors, resulting in higher joint gains. Additionally, only behavioral CQ (behavioral flexibility during intercultural interactions), but not other dimensions of CQ, predicted sequences of cooperative strategies. Our research adds to this stream of findings by demonstrating the effects of metacognitive CQ on intercultural creative collaboration. These findings collectively suggest that different dimensions of CQ seem to have specific distinct effects on interactions between individuals from different cultures. Thus, it is important that research on CQ be clear on what specific dimension of CQ is responsible for its predicted effects.

An interesting question is why the maximum metacognitive CQ in a dyad mattered in predicting its success on our creative collaboration task whereas the minimum motivational CQ in a dyad mattered in predicting its success on Imai and Gelfand’s (2010) negotiation task. In a negotiation task with fixed issues and option ranges, the solution is a selection from a preset permutation of possibilities. Selecting the solution that optimizes joint gains requires persistence and good faith cooperation from both sides, as each side has to reveal their preferences and make concessions. A skilled negotiator cannot find the win-win outcome if the other side is completely reticent or intransigent. This may be why motivational CQ mattered and specifically the weaker link of motivational CQ in the dyad. In a creative collaboration task, such our recipe challenge, success comes from a dyad combining disparate ideas to forge a novel solution. It is a much less structured decision problem. A major challenge lies in avoiding misunderstanding—in interpreting and appreciating the other’s ideas, likely at first to be unfamiliar and half-formed. Hence the relevant dimension of CQ would be that which enables the dyad’s mutual understanding and rapport. The communication gap can be bridged so long as at least one member of the conversation is good at taking the other’s perspective. This may be why metacognitive CQ mattered and specifically the stronger link of metacognitive CQ in the dyad.

Is it possible that metacognitive CQ, besides enhancing intercultural interactions, works through individuals who draw on knowledge from other cultures more effectively and ultimately come up with more novel ideas? In Study 3, we were able to check for the influence of individuals’ creativity and found that the effects of metacognitive CQ still hold even when the higher score of the

³ We thank an anonymous reviewer for this interesting insight.
two persons’ creativity score was controlled for. Hence, while it is plausible that metacognitive CQ might enable individuals to come up with better ideas during collaboration, individual level creativity before the interaction is unlikely to be the key driver to intercultural creative collaboration.

Practical implications

Findings from our research also have practical implications for promoting knowledge sharing and innovation in global teams and organizations. Global teams often face the challenge of getting members from different cultures and countries to work effectively with one another (Hagel & Brown, 2005). Research on teams and groups has been generally critical of training activities focused on affect and socio-emotional connections rather than on task-specific strategies (Moreland et al., 1996). However, our findings agree with recent integrative models suggesting that coaching designed to cultivate more emotional and personal connections may be particularly valuable early in a team’s work together (Hackman & Wageman, 2005). Establishing affect-based trust increases the likelihood that new ideas will be shared, without which a global team has little chance of leveraging its diversity for innovation.

In addition, the present research highlights the importance of cultural awareness in intercultural interactions. As managers develop their intercultural skills, it is important to note that acquiring knowledge about other cultures, although important, may not be sufficient for effective intercultural work. Managers need to build metacognitive strategies for managing cultural knowledge, knowing how to learn about other cultures in anticipation of intercultural encounters, and checking and updating assumptions during interactions in relation to the cultural environment (Ang et al., 2007; Shapiro et al., 2008). Practices for developing managers’ cultural metacognition include structured reflection and seeking generalizable lessons based on past intercultural experiences (Peterson, 2004; Ng, Van Dyne, & Ang, 2009). For instance, Ng and colleagues (2009) recommended that managers should actively reflect on their intercultural experiences and systematically document their insights and lessons learned in a journal. Keeping a journal would help managers identify strengths and weaknesses in their past intercultural experiences, consider what they could have done differently and what they can do differently the next time, and hence cultivate the habit of cultural metacognition.

Limitations and future research

As with all research, there are limitations to the present studies. A key concern is that cultural metacognition was measured solely based on self-report. Given that individuals who are unskilled on a given dimension often lack awareness of this (Kruger & Dunning, 1999), an externally assessed or objective measure of cultural metacognition might strengthen the evidence. To our knowledge, no objective assessment currently exists, yet researchers are developing ways to assess cultural metacognition as well as other dimensions of CQ using more objective tests. It would be interesting to see if these new forms of cultural metacognition assessment would yield similar results in future research.

Another limitation is that while we measured a specific behavioral aspect of creative collaboration, i.e., new idea sharing, there are likely to be other behavioral processes that might also be important. Thus, another direction for future research is to examine the specific behaviors of individuals with high vs. low cultural metacognition during the intercultural creative collaboration process. Do people with high cultural metacognition conduct conversations differently than those with low cultural metacognition? One approach would be to videotape the intercultural meetings and systematically code the various types of verbal and nonverbal behaviors. Individuals with high cultural metacognition may hedge their statements more and ask clarifying questions rather than making presumptuous statements.

The individual studies reported in this research have specific limitations. In Study 1, where the creative collaboration measure was a perception from other-culture associates, the question was worded in a way that could be interpreted as asking about both working relationships and creative collaboration success, whereas it would be better if asked about creative collaboration in working relationships. We acknowledged that in Study 2 the correlation between the two cognition-based trust items \(r = .65\), while significant, was somewhat low. Prior research by Chua et al. (2008), however, has found that this 2-item version of the cognition-based trust scale correlates highly \(r = .95\) with the corresponding complete scale from the McAllister (1995) study, so we believe the scale taps the desired construct. In the pilot study preparing for Study 3, a simple general trust measure was used rather than more detailed affect- and cognition-based trust measures, as it was not aiming to test the hypothesis incisively but merely check the efficacy of the conversation manipulation.

In Study 3, the two types of trust were measured as competing mechanisms. They cover the affective and cognitive dimensions of a nascent relationship that may drive creative collaboration success. Our results show that the affective dimension increases in the presence of personal communication and drives creative collaboration success, whereas the cognitive dimension does not. While the study provided a test between two theoretically plausible mediators and replicated the Study 2 findings in favor of the affective mechanism rather than the cognitive mechanism, it is always possible that there is some other intervening process that neither of our measured mediators captured, although it is not clear what it could be. Future research could attempt to rule out other mechanisms by measuring other dimensions of the relationship, beyond trust, and also by manipulating other conditions for the development of affect-based trust from cultural metacognition, besides personal communication. In sum, each of the individual studies has its limitations, and that is why we present four studies with varying methods that have complementary strengths. While there might be alternative accounts for particular studies, no alternative account can survive all the studies. As is typical in social psychology and micro-organizational behavior research, it is the package of studies that is incisive with regard to the thesis rather than one definitive, critical experiment.

Beyond addressing limitations of the present research, future research could also further probe the cognitive and physiological correlates of cultural metacognition. For example, one might use fMRI scans to distinguish brain regions that are activated when individuals with high cultural metacognition interact with someone of another culture. We would expect activation in areas involved in checking for conflicts and less activation in areas associated with stereotype use (Kerns et al., 2004; Lieberman, 2003). A recent study of male business students found that baseline testosterone levels, measured with salivary assays, are associated with lower cultural metacognition, less past work experience outside of one’s native culture, and less ongoing cooperation with classmates from cultural outgroups (Morris & Mor, 2012).

Finally, it is important to investigate what engenders cultural metacognition. Can it be enhanced via specific interventions? Klafeln and colleagues (2008) suggest that the development of cultural metacognition may depend on personality as well as environmental exposure. Multicultural experiences such as living abroad can provide individuals with opportunities to interact with people from other cultures, helping them to develop self awareness and skills in intercultural learning. However, not everyone can harness these opportunities to the fullest extent. Individuals low in the personality trait of openness to new experiences, for example,
might resort to cultural stereotypes to manage the uncertainties associated with interacting across cultures, preventing them from forming nuanced cognitive strategies for cross-cultural interactions. Although the argument that one's level of cultural metacognition depends on the interaction between personality traits and prior cultural experiences seems plausible, it has not been empirically tested. Research that explores such cross-cultural effects would make a valuable contribution.

**Conclusion**

The current research has clear theoretical and practical implications for understanding and promoting creativity, innovation, and problem solving in multicultural global contexts. Managers hoping for creative collaborations with people of different cultures should be advised to cultivate cultural metacognition. Cultural metacognition helps individuals to navigate intercultural interactions and thereby fosters affect-based trust and ultimately creative collaboration. To date, there has been little research that directly examines how creative work between people of different cultures can be enhanced. We believe our research serves as an important step toward stimulating investigations in this area.
